## Alignment-wide estimates

- Using standard MLE approaches it is straightforward to obtain point estimates of  $dN/dS := \beta/\alpha$
- Can also easily test whether or not dN/dS > 1, or < 1 using the likelihood ratio test (LRT)</li>
- Codon models also support the concepts of synonymous and nonsynonymous distances between sequences using standard properties of Markov processes (exponentially distributed waiting times)

# Three example datasets

#### West Nile Virus NS3 protein

- An interesting case study of how positive selection detection methods lead to testable hypotheses for function discovery
- Brault et al 2007, A single positively selected West Nile viral mutation confers increased virogenesis in American crows

### HIV-1 transmission pair

- Partial *env* sequences from two epidemiologically linked individuals
- An example of multiple selective environments (source, recipient, transmission)

### SARS-CoV-2 Spike

- Full length spike sequences chosen to represent viral diversity (circa mid 2021)
- Good example for analyzing selection in population samples with many "deadend" intra-host variants
