## Any questions on the previous material?

## We have covered:

- Brief background and examples of natural selection
- dN/dS as a tool to measure the action of natural selection, explained using the first counting method for estimating dN/dS (Nei-Gojobori, 1986) and its extensions
- Next section: Codon substitution models the basis of modern (1998-) dN/dS estimation approaches

## Codon-substitution models

- In 1994, first tractable mechanistic evolutionary models for codon sequences were proposed by **Muse and Gaut** (MG94), and, independently, by **Goldman and Yang** (GY94) [in the same issue of MBE, back to back]
- Markov models of codon substitution provide a powerful framework for estimating substitution rates from coding sequence data, as they
  - encode our mechanistic understanding of the evolutionary process,
  - enable one to compute the phylogenetic likelihood,
  - permit hypothesis testing or Bayesian inference,
  - systematically account for confounding processes (unequal base frequencies, nucleotide substitution biases, etc.),
  - afford many opportunities for extension and refinement (still happening today).

A likelihood approach for comparing synonymous and nonsynonymous nucleotide substitution rates, with application to the chloroplast genome
